GR-104 Diabetic Retinopathy Detection Without Pre-Processing

Author: Suman Bharti & Swetha Pailla  Advisor: Dr. Mohammed Aleldhari

Abstract
This Diabetic retinopathy is an eye condition that can lead to vision loss and blindness in people who have diabetes. To detect DR is a time-consuming and manual process that requires a trained clinician to examine and evaluate the color fundus images of retina. Pre-processing for retinal images is important for DR detection to achieve higher accuracy but, it might require domain knowledge for doing such standard pre-processing steps. Our goal is to develop automated detection system for 5 DR stages 0-No DR, 1-Mild, 2-Moderate, 3-Severe, 4-Proliferative DR without pre-processing steps.

Introduction
Diabetic retinopathy is an eye condition that can lead to vision loss and blindness in people who have diabetes. The US Center for Disease Control and Prevention estimates that 29.1 million people in the US have diabetes and WHO estimates that 347 million people have this disease worldwide. Diagnosis of DR is an intensive process, which involves a lot of clinical study and requires time, resources and money.

Research Question(s)
1. In medical field, DR detection is time consuming, and it requires appropriate equipment.
2. The expertise and equipment required are often lacking in areas where the rate of diabetes in local populations is high and DR detection is most needed.
3. Pre-processing techniques are heavily dependent on domain knowledge with high computation time.
4. Early detection of DR through regular screening is a key to prevent blindness and preserve good vision in diabetes sufferers.
5. Goal is to develop automated detection system for multistage DR detection without pre-processing step.

Materials and Methods
A large set of high-resolution retina images are taken under a variety of imaging conditions of EyePACS[1] dataset from Kaggle Diabetic Retinopathy Detection - Identify signs of diabetic retinopathy in eye images. We omitted all the pre-processing techniques as it is heavily dependent on domain knowledge with high computation time. We use Capsule Neural Network (CapsNet) which adopts the concept of capsules to address the weakness in existing algorithms. Capsule neural network helps to perform the functions of a CNN with improved architecture and with more robust classification.

Conclusions
Without doing any pre-processing techniques on retinal images is a cost-effective strategy to solve the problem of multistage DR detection. As Pre-processing techniques are heavily dependent on domain knowledge with high computation time. Using CapsNet (Capsule Neural Network) model, we achieve the average accuracy (76%) without pre-processing techniques with reduced computation time. The dataset used for our experiment is unbalanced for 5 class distribution. If we use an improved dataset, then the results can be improved.

Acknowledgments
This work is completed with the constant support and guidance by Dr. Mohammed Aleldhari. His constant feedback to improve the research questions and results lead us to achieve the successful results. His CST3673 contributes to evolve the thought process, in choosing the critical need of research question, what is known, gap in knowledge, proposal objectives, hypothesis, rationale, goals, outcomes and impact of research in society.
